Notation 1

In the following notation, pay attention to the subscript, as it tells you whether we refer to input (i), hidden (j) or output (k) units. I also use p, q and r for each of the three layers when talking about a specific connection. Although in principal each hidden and output neuron can have a bias unit, we often assume it is yet another input (which does not receive input) and so biases are omitted here.

Term	Meaning
а	Total input to a unit
y	Output of a unit
i, p	Subscript for input units
j, q	Subscript for hidden units
k, r	Subscript for output units
w_{ij}	Weight from input unit i to hidden unit j
w_{ik}	Weight from hidden unit j to output unit k
Δw_{ij}	Weight change from unit i to unit j

Calculating Network Activation

We will train the network to learn the association between given inputs x_i and their desired outputs t_k . Unit activations, a_i , and outputs, y_i , of hidden layer units are calculated by:

Hidden layer
$$a_j = \sum_i w_{ij} y_i$$
 (1)

$$y_j = g(a_j) \tag{2}$$

$$y_{j} = g(a_{j})$$
 (2)
Output layer $a_{k} = \sum_{j} w_{jk} y_{j}$ (3)

$$y_k = g(a_k) \tag{4}$$

Error function
$$E = \frac{1}{2} \sum_{k} (t_k - y_k)^2$$
 (5)

 $g(\cdot)$ is some transfer function, typically sigmoidal or the identity. We wish to make a learning rule:

$$\Delta w_{ij} = -\eta \frac{\partial E}{\partial w_{ij}}$$

2 Back propagation

Step 2a: Updating weights from hidden to output layer, w_{jk}

If we pick one weight w_{qr} to adapt, then we want to see how the error changes in response to a change to that weight. So, from 5:

$$\frac{\partial E}{\partial w_{qr}} = -\sum_{k} (t_k - y_k) \frac{\partial y_k}{\partial w_{qr}}$$

If we change w_{qr} , the only y_k that changes is when when k=r, so $\frac{\partial y_k}{\partial w_{qr}}=0$ except when k=r:

$$\frac{\partial E}{\partial w_{qr}} = -(t_r - y_r) \frac{\partial y_r}{\partial w_{qr}}$$

Now recall that $y_r = g(a_r)$ and $a_r = \sum_j w_{jr} y_j$ so

$$\frac{\partial y_r}{\partial w_{qr}} = g'(a_r) \frac{\partial a_r}{\partial w_{qr}}$$

$$\frac{\partial a_r}{\partial w_{qr}} = y_q \qquad ("partial trick")$$

$$\frac{\partial E}{\partial w_{qr}} = -(t_r - y_r)g'(a_r)y_q$$
Let
$$\delta_k = g'(a_k)(t_k - y_k)$$
So
$$\frac{\partial E}{\partial w_{qr}} = -\delta_r y_q$$

Step 2b and 2c: Updating weights from input to hidden layer, w_{pq}

If we change any weight w_{pq} , this can change the activation of hidden unit y_j and so affect all output layer units, not just one output unit as for hidden-to-output layer.

$$\frac{\partial E}{\partial w_{pq}} = -\sum_{k} (t_k - y_k) \frac{\partial y_k}{\partial w_{pq}}$$

Apply the chain rule via y_q to get the derivative

$$\begin{split} \frac{\partial y_k}{\partial w_{pq}} &= \frac{\partial y_k}{\partial y_q} \frac{\partial y_q}{\partial w_{pq}} \\ \frac{\partial y_k}{\partial y_q} &= g'(a_k) \frac{\partial a_k}{\partial y_q} = g'(a_k) w_{qk} \qquad \text{from 3, 4 and "partial trick"} \\ \frac{\partial y_q}{\partial w_{pq}} &= g'(a_q) \frac{\partial a_q}{\partial w_{pq}} = g'(a_q) y_p \qquad \text{from 1, 2} \end{split}$$

Plugging them all back together we get:

$$\frac{\partial E}{\partial w_{pq}} = -\sum_{k} (t_k - y_k) \times g'(a_k) w_{qk} \times g'(a_q) y_p$$

$$= -y_p g'(a_q) \sum_{k} (t_k - y_k) g'(a_k) w_{qk}$$

$$= -y_p g'(a_q) \sum_{k} \delta_k w_{qk}$$
Let
$$\delta_q = g'(a_q) \sum_{k} \delta_k w_{qk}$$

$$\frac{\partial E}{\partial w_{pq}} = -\delta_q y_p$$

So, errors **back-propagate**: travel in opposite direction to activity to generate internal errors δ_q .
